PRN:- 202501090087

2.1.1. List operations

33:51

Write a Python program that implements a menu-driven interface for managing a list of integers. The program should have the following menu options:

1. Add

2. Remove

3. Display

4. Quit

The program should repeatedly prompt the user to enter a choice from the menu. Depending on the choice selected, the program should perform the following actions:

Add: Prompts the user to enter an integer and add it to the integer list. If the input is not a valid integer, display "Invalid input".

Remove: Prompts the user to enter an integer to remove from the list. If the integer is found in the list, remove it; otherwise, display "Element not found". If the list is empty, display "List is empty".

Display: Displays the current list of integers. If the list is empty, display "List is empty".

Quit: Exits the program.

The program should handle invalid menu choices by displaying "Invalid choice". Ensure that the program continues to prompt the user until they choose to quit (option 4).

Input:-

```
list=list()
```

while True:

print("1. Add")

print("2. Remove")

print("3. Display")

print("4. Quit")

n=int(input("Enter choice: "))

if n == 1:

add = int(input("Integer: "))

list.append(add)

print(f"List after adding: {list}")

elif n == 2:

if len(list) == 0:

print("List is empty")

elif len(list)!= 0:

remove=int(input("Integer: "))

if remove not in list:

print("Element not found")

else:

list.remove(remove)

print(f"List after removing: {list}")

elif n == 3:

if len(list) == 0:

print("List is empty")

else:

print(list)

elif n == 4:

break

else:

print("Invalid choice")

The screenshot displays the CodeTANTRA IDE interface. On the left, a code editor shows a Python program for '2.1.1. List operations'. The program implements a menu-driven interface for managing a list of integers. The menu options are: 1. Add, 2. Remove, 3. Display, 4. Quit. The program repeatedly prompts the user to enter a choice. Depending on the choice, it performs specific actions: Add (adds an integer to the list), Remove (removes an integer from the list), Display (shows the current list), and Quit (exits the program). It also handles invalid menu choices by displaying 'Invalid choice' and continuing to prompt the user. The right side of the IDE shows the test results. It indicates that 2 out of 2 shown test cases passed and 1 out of 1 hidden test cases passed. The test results table shows the expected output and actual output for each test case, including the user input and the resulting list state.

2.1.1. List operations 33:51

Write a Python program that implements a menu-driven interface for managing a list of integers. The program should have the following menu options:

1. Add
2. Remove
3. Display
4. Quit

The program should repeatedly prompt the user to enter a choice from the menu. Depending on the choice selected, the program should perform the following actions:

- **Add:** Prompts the user to enter an integer and add it to the integer list. If the input is not a valid integer, display "Invalid input".
- **Remove:** Prompts the user to enter an integer to remove from the list. If the integer is found in the list, remove it; otherwise, display "Element not found". If the list is empty, display "List is empty".
- **Display:** Displays the current list of integers. If the list is empty, display "List is empty".
- **Quit:** Exits the program.
- The program should handle invalid menu choices by displaying "Invalid choice". Ensure that the program continues to prompt the user until they choose to quit (option 4).

2.1.2. Dictionary Operations

19:18

Write a Python program to perform insertion, update, deletion, and traversal operations on a dictionary. An initial dictionary containing 10 predefined records is already given in the program.

Operations to be Performed:

Insertion – Insert a new key-value pair into the dictionary using user input.

Update – Update the value of an existing key using user input.

Deletion – Delete a specified key from the dictionary using user input.

Traversal – Traverse the final dictionary and display all key-value pairs.

Input and Output Format:

Read an integer representing the key to be inserted and a string representing its value. Insert this new key-value pair into the dictionary and display the dictionary after insertion.

Read an integer representing the key to be updated and a string representing the new value. Update the value of the specified key (only if it exists) and display the dictionary after the update.

Read an integer representing the key to be deleted. Delete the specified key from the dictionary (only if it exists) and display the dictionary after deletion.

Finally, traverse the dictionary and display all key-value pairs.

The program should also display the original dictionary before performing any operations. Each output should be printed with appropriate messages.

Note:

All operations must be performed using dictionary methods.

Perform deletion only if possible; leave the dictionary unchanged.

Refer to the visible test cases for better understanding and strictly match with the input/outputs.

Input:-

Initial dictionary with 10 predefined records

```
student = {  
    1: "Amit",  
    2: "Riya",  
    3: "Kiran",  
    4: "Neha",  
    5: "Arjun",  
    6: "Pooja",  
    7: "Rahul",  
    8: "Sneha",
```

```
9: "Vikram",  
10: "Anjali"  
}  
  
print("Original Dictionary:",student)  
  
key1=int(input())  
  
value1=input()  
  
student.update({key1:value1})  
  
print("After Insertion:",student)  
  
key2=int(input())  
  
value2=input()  
  
if(key2 in student.keys()):  
    student.update({key2:value2})  
  
print("After Update:",student)  
  
key3=int(input())  
  
if(key3 in student.keys()):  
    student.pop(key3)  
  
print("After Deletion:",student)  
  
print("Traversing Dictionary:")  
  
for key,value in student.items():  
    print(f"{key} : {value}")
```

2.2.1. Linear search Technique

28:50

Write a program to check whether the given element is present or not in the array of elements using linear search.

Input format:

The first line of input contains the array of integers which are separated by space

The last line of input contains the key element to be searched

Output format:

If the element is found, print the index. If the element found multiple times, print the starting index

If the element is not found, print **Not found**.

Sample Test Case:

Input:

1 2 3 4 3 5 6

3

Output:

2

The screenshot shows the CodeTANTRA IDE interface. On the left, a problem titled "2.2.1. Linear search Technique" is displayed with a timer at 28:50. The problem description asks for a program to check if an element is present in an array using linear search. It specifies the input format (array and key) and output format (index or "Not found"). A sample test case is provided with input "1 2 3 4 3 5 6", key "3", and output "2". Below the problem description is a "Sample Test Cases" button. On the right, the "Debugger" panel shows the execution results. It indicates that 2 out of 2 shown test cases passed and 2 out of 2 hidden test cases passed. The average time is 0.008 s (8.25 ms) and the maximum time is 0.009 s (9.00 ms). Two test cases are detailed: Test case 1 with input "1 2 3 4 3 5 6" and key "3", and Test case 2 with input "1 2 3 4 5 6 7 8 9 19" and key "20". Both test cases show the expected output matching the actual output.

INPUT:-

```
def linear_search(arr, key):  
    for i in range(len(arr)):  
        if arr[i] == key:  
            return i  
    return -1  
  
arr = list(map(int, input().split()))  
key = int(input())  
result = linear_search(arr, key)  
if result != -1:
```

```
print(result)
```

else:

```
print("Not found")
```

2.2.2. Captain of the Team

03:34

You are provided with the heights of 11 cricket players (in centimeters). Your task is to identify the tallest player, who will be selected as the captain of the team.

Input Format:

The first line of input will contain 11 integers, each representing the height of a player (in centimeters), each separated by a space.

Output Format

The output should be the height (in centimeters) of the tallest player.

Input:-

```
heights=list(map(int,input().split()))
```

```
tallest_player=max(heights)
```

```
print(tallest_player)
```

2.2.2. Captain of the Team

03:34

You are provided with the heights of 11 cricket players (in centimeters). Your task is to identify the tallest player, who will be selected as the captain of the team.

Input Format:

The first line of input will contain 11 integers, each representing the height of a player (in centimeters), each separated by a space.

Output Format

The output should be the height (in centimeters) of the tallest player.
